## Improving Commercial Value Estimates Using a New Cost Model

## IAAO Annual Conference

Tampa, Florida August 28-31, 2016
Tuesday Morning, 10:00 AM - 11:00 AM
This presentation contains copyrighted illustrations that have been removed from the version intended to be reproduced and distributed. The live conference presentation contains the copyrighted material as permitted under the "Fair Use" doctrine for educational purposes.

## Question

Is "That's the way we've always done it" a good reason to keep doing something the same way?

## Learning Objectives

Gain an understanding of how cost schedules are constructed

Learn about weaknesses in the cost estimating methods currently being widely used

Learn how weaknesses can be corrected with a modern model and methodology

Recognize that existing methods can always be improved

## Why Is The Cost Approach Important?

- Obviously, it is one of the three approaches to value
- It is much more important for commercials \& industrials than for residentials, which usually have sufficient sales
- An active, verifiable sales market that satisfies the USPAP standard is frequently difficult to obtain for C \& I
- When up-to-date cost models and current, accurate cost sources are available, the cost approach may provide the only factually verifiable evidence of value

## What are the Benefits of the New Method?

\#1 Greater accuracy of cost estimates
\#2 More choices of correct shell structure type
\#3 More flexibility in configuring interior occupancies
\#4 Ability to quality grade shell \& interior separately
\#5 More flexibility in separately applying depreciation
\#6 Much easier to handle changes in occupancy uses
\#7 Easier to handle depreciation after remodeling

## COST SCHEDULE CONSTRUCTION Vertical, Horizontal, and Finish Costs

1 Structural Vertical Costs - Exterior Walls
2 Structural Horizontal Costs - Frame, Roof \& Floors
3 Finish Vertical Costs - Partitions, Doors, Wall Finish
4 Finish Horizontal Costs - Floor Finish, Ceiling Finish
5 Electrical Requirements for the intended use
6 Plumbing Requirements for the intended use
7 Use Heating, Ventilation, Air Conditioning (HVAC)

## COST SCHEDULE CONSTRUCTION

- Structural Vertical \& Horizontal Costs plus Frame determine the building "Structural Shell Cost"
- Interior Finish Vertical \& Horizontal Costs, Electrical, Plumbing, and HVAC Costs are determined by the intended use of the building or building section
- Nearly any type interior finish for any particular intended use can be placed in any type of Building Shell Structure
- Over the past 40 years Building Codes have tightened

## Appraisal Cost Approach Estimating vs. Builder Job Cost Estimating

- Same Cost Elements Apply:
- Material Cost
- Labor Cost
- Equipment Cost
- Builder Overhead $\&$ Profit
- What is Different?
- Builder works from a specific building plan
- Appraiser must work from an abstract "model"
- Which is a representation of what is typical
- Which includes many assumptions

## What is an Appraisal Cost Model?

- An Appraisal Cost Model is a description of the characteristics of a typical building that most closely resembles a specific or "subject" building
- An Appraisal Cost Model contains assumptions about what is typical for each building type described
- The various described building types must be organized and classified for ease and efficiency of use in appraisal and for accurate association of the building type assumptions with current industry material, labor, and equipment costs

## Industry Cost Sources

- Where are current industry material, labor, and equipment costs found?

## Examples of Published Cost Data

## RS Means 2016 Square Foot Costs Book Page 351

## Examples of Published Cost Data

Reinforced Concrete Block Wall Costs from Three Publications

| 8" Block Per Sq. Ft. of Wall: |  |  |  |  | With |
| :--- | :---: | :--- | :--- | :--- | :--- |
| RS Means Sq. Ft. Costs |  |  | Labor | Total | O\& P |
| Craftsman NCE | 3.13 | 7.55 | $11.68^{*}$ | 14.60 |  |
| Marshall Valuation Service | n/a | n/a | 8.59 | to | $12.50 *$ |

* Does not include architect fees, builder overhead \& profit (0 \& P), add 25\% * Includes normal builder overhead \& profit, but not architect fees (Section 1 p 8)

## Example Wall Cost Model Calculation

## For Various Wall Heights and Exterior Wall Cover Types

This illustration has been removed from the version reproduced for distribution

## Putting It All Together For The Cost Table

The Traditional Way of Creating A Cost Table

All assemblies and components of a "typical" building of a particular type, such as office, are calculated as done in the previous slide for walls

The individual costs are totaled for a representative size or multiple sizes (Sq Ft areas) of the building type being studied, including the office interior finish in this case
The total building cost for the office use is then divided by the Sq Ft area to determine the base cost per Sq Ft

## Example for a 7000 SF Office Building

Width x Length
Area
Perimeter
Wall Height
Vertical (wall) cost, 380 LF @ \$368.15
Horizontal Shell cost, 7000 SF @ \$21.46
Office Use Finish 7000 SF @ \$43.82 + Entry
General, Overhead \& Profit, Architect @ 25\%
Total Building Cost
Cost per Square Foot

* Using Craftsman 2016 National Cost Estimator

## Costing Results Three 2016 National Publications

7,000 SF Office Building, $50 \times 140$, 12' WH, 380 Perimeter
$\begin{array}{ll}\text { RS Means Square Foot Costs Book, p. } 174 & \$ 1,252,300 \\ \text { Craftsman Nat'l Building Cost Manual p. } 140 & \$ 1,157,500 \\ \text { Marshall Valuation Service Book, Sec } 15 \text { p. } 17 & \$ 809,850 * \\ \text { *Class C, Average Quality, .9635 combined multipliers } & \\ \text { NOTE: The above costing results are based on Square Foot rates by Type of Use }\end{array}$
New Cost Model using direct calculation (prior slide) \$ 751,450

## Traditional Cost Manual Organization

First Organizational Level:
Second Organizational Level:
Third Organizational Level:
Further Adjustments:

Use/Occupancy of Building
5 Classes of Construction
Quality of Construction
Perimeter/Area Factor Wall Height Factor
Month/Year Adjustment

## Traditional Cost Manual Organization

This illustration has been
removed from the version
reproduced for distribution

IAAO206

## Traditional Cost Manual Organization Descriptive Specifications

This illustration has been removed from the version<br>reproduced for distribution

## Notes:

The quality TYPE within class actually describes the type of wall
Notice that the building structure type changes with quality
In mass appraisal, quality "grade" has a somewhat different meaning

## Weaknesses of the Traditional Cost Manual Organizational Approach

Traditional cost manual organization is not logical when you consider modern building construction methods:

The building shell structure is built first using one structural type, then
One or more interior finishes are applied based on the intended uses From the traditional cost manual, square foot rates are applied to the building or use area that include all costs: vertical, horizontal, use finish

Multipliers are applied in an attempt to compensate for method errors
Too few structure types (classes) are available for precise costing and the classes actually contain a mixture of structural types
Many buildings have multiple uses (occupancies) creating complications
The traditional cost manual approach was devised before computerization

## Is There a Better Method of Costing?

1 Separate the building shell costing from use finish costing
2 Use more building structure types that are more precise
The most commonly applied construction class is too broad:
Requires masonry walls but allows wood floor $\&$ roof joists
Lumps too many structure types into one classification
Results in an average cost applied to many different types
3 Make use of the computer's capacity to handle detail
Compute exterior wall costs directly based on length $\&$ height Allow greater and more precise selection of exterior wall type
4 Allow user to select from many interior uses to define interior Allow unlimited number of uses in any structure classification Allow separate structural shell and interior finish depreciation

## New Building Structure Types

|  | CLASSIFICATIONS |  |  |
| :--- | :---: | :---: | :---: | :---: |
| 1- Light wood or steel stud frame (residential) | FEMA | IBC | MVS |
| 2- Heavier wood or steel stud frame (light commercial) | W1 | V | D |
| 3- Unreinforced masonry walls, wood joists (both residential \& commercial) | URM | III | C |
| 4- Reinforced masonry walls, metal joists, decks w/concrete fill | RM2 | IIA | C |
| 5- Pre-cast tilt-up concrete wall buildings, metal joists, decks w/conc fill | PC1 | IIA | C |
| 6-Engineered wood post frame (called pole buildings 30 years ago) | W1A | IV | DpoLE |
| 7- Pre-engineered steel frame | S3 | IIB | S |
| 8-Structural steel frame with fire resistant coatings | S1 | IB | A/B |
| 9-Steel reinforced concrete frame, highly fire resistant, nearly fireproof | C1 | IA | A/B |

## Type 1: Light wood or steel stud frame (residential)

## 1-Light wood or steel stud frame (residential)

These buildings are single or multiple family dwellings of one to three stories in height. Building loads are light and the framing spans are short. Floor and roof framing consists of wood joists or rafters on wood studs spaced 16 inches apart. The first floor framing is supported directly on the foundation, or post and beam supports. The foundation consists of spread footings constructed with cast-in-place concrete or concrete masonry block. Lateral forces are resisted by wood frame diaphragms and shear walls.
Floor and roof diaphragms consist of straight or diagonal lumber

sheathing, tongue and groove planks, oriented strand board, or plywood. Shear walls consist of exterior plywood or oriented strand board sheathing with a wide variety of exterior cover materials such as vinyl, wood, hardboard, fiberboard, metal, stucco, including masonry veneers such as brick and various types of stone. Interior partitions are sheathed with gypsum board.

## Type 2: Heavier wood or steel stud frame (light commercial)

## 2-Heavier wood or steel stud frame (light commercial)

These buildings are usually commercial or industrial with larger
 floor areas. There are few, if any, interior load bearing walls. The floor and roof framing consists of wood or steel trusses, glulam or steel beams, and wood posts or steel columns. Lateral forces are resisted by wood diaphragms and exterior stud walls sheathed with plywood, oriented strand board, stucco, plaster, straight or diagonal wood sheathing, or braced with rod bracing. Wall openings for storefronts and garages, when present, are framed by post-and-beam framing.

## Type 3: Unreinforced masonry walls, wood joists (both residential \& commercial)

## 3-Unreinforced masonry walls, wood joists (both residential \& commercial)

These buildings have perimeter bearing walls that consist of
footings.
unreinforced masonry, frequently concrete block. Interior bearing walls, when present, also consist of unreinforced masonry. Floors consist of structural panel or plywood sheathing rather than lumber sheathing. The diaphragms are flexible relative to the walls. When they exist, ties between the walls and diaphragms consist of bent steel plates or anchors embedded in the mortar joints and attached to framing. Foundations consist of concrete-spread

## Type 4: Reinforced masonry walls, metal joists, decks w/concrete fill

4-Reinforced masonry walls, metal joists, decks w/concrete fill

These building have reinforced masonry load bearing walls and floors that consist of metal deck with concrete fill, precast concrete planks, tees, or double-tees, with or without a cast-inplace concrete topping slab, and are stiff relative to the walls. The floor and roof framing is supported on interior steel or concrete frames or interior reinforced masonry walls.

## Type 5: Pre-cast tilt-up concrete walls with metal joists, concrete filled decks

## 5-Pre-cast tilt-up concrete wall buildings, metal joists, decks w/conc fill

These buildings are one or more stories in height and have precast concrete perimeter wall panels that are cast on site and tilted into place. Floor and roof framing consists of precast elements, cast-inplace concrete, or metal deck with concrete fill, and are stiff relative to the walls. Framing is supported on interior steel columns and perimeter concrete bearing walls. Lateral forces are resisted by the precast concrete perimeter wall panels. Wall panels may be solid, or have large window and door openings which cause

the panels to behave more as frames than as shear walls. Foundations consist of concrete-spread footings or deep
pile foundations.

## Type 6: Engineered wood post frame (called pole buildings 30 years ago)

## 6-Engineered wood post frame (called pole buildings 30 years ago)

These buildings feature large, solid sawn posts or laminated columns instead of wood studs, steel framing, or concrete masonry. Post-frame construction is an engineered wood-frame building system that meets UBC and IBC standards. They transfer loads to the ground or surface-mounted to a concrete pier or masonry foundation, and may use plastic barrier systems for enhanced protection of wood and concrete posts or piers. Post-frame structures are more quickly erected than other kinds of buildings. Because the larger posts and the interlocking frame can handle greater loads than stud-wall construction, fewer
 structural materials are needed, which saves time and other costs. Also, because posts are spaced farther apart than studs, post-frame buildings feature an exceptionally large wall cavity and provide ample room for insulation, lowering heating and cooling costs through the life of the building. Almost any type of exterior façade may be installed on post-frame buildings, which can be designed to meet the highest standards for quality and aesthetics. Post-frame construction is an efficient and economical option for low-rise applications and is now the construction method of choice for any number of commercial, industrial, municipal, residential, religious, and agricultural projects.

## Type 7: Pre-engineered steel frame

## Pre-engineered steel frame

These buildings are pre-engineered and prefabricated with transverse rigid steel frames. They are one story in height. The roof and walls consist of lightweight metal, fiberglass or similar panels. The frames are designed for maximum efficiency and the beams and columns consist of tapered, built-up sections with thin plates. The frames are built in segments and assembled in the field with bolted or welded joints. Lateral forces in the transverse direction

elements or rod bracing. Diaphragm forces are resisted by untopped metal deck, roof panel shear elements, or a system of tension rod bracing.

82nd Annual International Conference on Assessment Administration

## Type 8: Structural steel frame with fire resistant coatings

## Structural steel frame with fire resistant coatings

These buildings consist of a frame assembly of steel beams and steel columns. Foundations consist of concrete-spread footings or deep pile foundations. Floor and roof framing consists of cast-inplace concrete slabs or metal deck with concrete fill supported on steel beams, open web joists, or steel trusses. Lateral forces are resisted by steel moment frames that develop their stiffness through rigid or semi-rigid beam-column connections. When all connections are moment-resisting connections, the entire frame

participates in lateral force resistance. Diaphragms consist of concrete or metal deck with concrete fill and are stiff relative to the frames. A steel building's structural members are expected to have fire resistance to prevent structural failure for a determined period of time to give the building occupants more time to escape and allow the fire service to control it. The required fire resistance periods for the different steel

building types are found in local building codes. The structural steel needs to be protected against fire using the proper insulating materials and methods to protect the structural steel members and allow them to resist weakening for longer periods. Recent research has been conducted resulting in several fire-resistant steels with better strength levels developed. These steels represent a notable improvement over conventional steels in terms of elevated temperature yield strength. Exterior walls consist of metal panel curtain walls, glazing, brick masonry, or

precast concrete panels. When the interior of the structure is finished, frames are concealed by ceilings, partition walls, and architectural column furring.

## Type 9: Steel reinforced concrete frame highly fire resistant, nearly fireproof

Steel reinforced concrete frame, highly fire resistant, nearly fireproof

These buildings consist of a frame assembly of cast-in-place concrete beams and columns. Floor and roof framing consists of cast-in-place concrete slabs, concrete beams, one-way joists, twoway waffle joists, or flat slabs. Lateral forces are resisted by concrete moment frames that develop their stiffness through monolithic beam-column connections. Modern frames in regions of high seismicity have joint reinforcing, closely spaced ties, and special detailing to provide ductile performance. This detailing is not present in older construction. Exterior walls consist of metal panel curtain walls, glazing, brick masonry, or precast concrete
 panels. Foundations consist of concrete-spread footings or deep pile foundations.

## Nine Exterior Cover (Cladding) Groups

## Nine Exterior Cover (Cladding) Groups

Group 1 Vinyl, Hardboard, T-1-11, OSB, Plywood panels, and similar cost cladding Group 2 Galvanized steel siding, fiber cement siding, and similar cost cladding
Group 3 Alum siding, pine siding, stucco, and similar cost cladding
Group 4 Cedar shingles, Nailite thermoplastic resin siding, redwood siding, log cabin siding
Group 5 Adobe block or concrete block, replacing stud wall
Group 6 EIFS - Exterior Wall Insulation and Finish System
Group 7 Brick veneer cladding or curtain wall
Group 8 Stone veneer or glass cladding or curtain wall; solid log load-bearing walls
Group 9 Solid stone cut blocks such as limestone 18 " thick

## Combining Structure Type with Exterior Cladding Group

This illustration has been removed from the version reproduced for distribution

## Greater Precision Cost Approach Estimating

Combining the choice of 9 building structure types with 9 possible exterior cover types for an unlimited number of wall segments of different wall heights produces much greater cost estimating accuracy

The new method uses the same data that has always been collected for commercial costing: Square foot area, perimeter, wall height \& type
The accuracy improvements come from having more refined structure type classifications, more choices of wall material, and direct computation of wall cost rather than converting wall cost to sq. ft. area

## Costing An Actual New Mega Warehouse Completed in 2015 in Louisville KY

Dimensions: 450' x 700' Area: 315,000 SF Perimeter: 2,300 LF Wall height: 32 ft

Structure Type 5: Tilt-up concrete panel wall

## What are the Benefits of the New Method?

\#1 Greater accuracy of cost estimates
\#2 More choices of correct shell structure type
\#3 More flexibility in configuring interior occupancies
\#4 Ability to quality grade shell \& interior separately
\#5 More flexibility in separately applying depreciation
\#6 Much easier to handle changes in occupancy uses
\#7 Easier to handle depreciation after remodeling

## Q\& A
